METHOD AND SYSTEM FOR DETERMINING THE PATH BETWEEN TWO POINTS OF AN IP NETWORK OVER WHICH DATAGRAMS ARE TRANSMITTED

5

Technical field of the invention

The present invention is directed to computer networks, and more particularly to a method and system, for determining from a network management device, the transmission path of datagrams sent between two points of an Internet Protocol (IP) network.

10

Background art

Internet

The Internet is a global network of computers and computers networks (the "Net"). The Internet connects computers that use a variety of different operating systems or languages, including UNIX, DOS, Windows, Macintosh, and others. To facilitate and 15 allow the communication among these various systems and languages, the Internet uses a language referred to as TCP/IP ("Transmission Control Protocol/Internet Protocol"). TCP/IP protocol supports three basic applications on the Internet :

- transmitting and receiving electronic mail,
- logging into remote computers (the "Telnet"), and
- transferring files and programs from one computer to another ("FTP" or "File Transfer Protocol").

TCP/IP

The TCP/IP protocol suite is named for two of the most important protocols:

- a Transmission Control Protocol (TCP), and
- an Internet Protocol (IP).

Another name for it is the Internet Protocol Suite. The more common term TCP/IP is used to refer to the entire protocol suite. The first design goal of TCP/IP is to build 25 an interconnection of networks that provide universal communication services : an "internetwork", or "internet". Each physical network has its own technology

dependent communication interface, in the form of a programming interface that provides basic communication functions running between the physical network and the user applications. The architecture of the physical networks is hidden from the user. The second goal of TCP/IP is to interconnect different physical networks to 5 form what appears to the user to be one large network.

TCP is a transport layer protocol providing end to end data transfer. It is responsible for providing a reliable exchange of information between 2 computer systems. Multiple applications can be supported simultaneously over one TCP connection between two computer systems.

- 10 IP is an internetwork layer protocol hiding the physical network architecture below it. Part of the communicating messages between computers is a routing function that ensures that messages will be correctly directed within the network to be delivered to their destination. IP provides this routing function. An IP message is called an IP Datagram.
- 15 Application Level protocols are used on top of TCP/IP to transfer user and application data from one origin computer system to one destination computer system. Such Application Level protocols are for instance File Transfer Protocol (FTP), Telnet, Gopher, Hyper Text Transfer Protocol (HTTP).

World Wide Web

- 20 With the increasing size and complexity of the Internet, tools have been developed to help find information on the network, often called navigators or navigation systems. Navigation systems that have been developed include standards such as Archie, Gopher and WAIS. The World Wide Web ("WWW" or "the Web") is a recent superior navigation system. The Web is :
 - 25 • an Internet-based navigation system,
 - an information distribution and management system for the Internet, and
 - a dynamic format for communicating on Internet.

The Web seamlessly, for the use, integrates format of information, including still images, text, audio and video. A user on the Web using a graphical user interface

- 30 may transparently communicate with different host computers on the system, and different system applications (including FTP and Telnet), and different information formats for files and documents including, for example, text, sound and graphics.

IP Router

One of the basic function of IP is its ability to form connections between different physical networks. This is due to the flexibility of IP to use almost any physical network below it, and to the IP routing algorithm. A system that builds connections between networks is termed a "router". A "Router" is a computer that interconnects two networks and forwards messages from one network to the other. Routers are able to select the best transmission path between networks. The basic routing function is implemented in the IP layer of the TCP/IP protocol stack, so any host (or computer) or workstation running TCP/IP over more than one interface could, in theory, forward messages between networks. Because IP implements the basic routing functions, the term "IP Router" is often used. However, dedicated network hardware devices called "Routers" can provide more sophisticated routing functions than the minimum functions implemented in IP.

IP Routing

When data is sent to a remote destination, each IP datagram is first sent to a local router. An incoming datagram that specifies a destination IP address other than one of the local router IP address is treated as a normal outgoing datagram. This outgoing datagram is subject to the IP routing algorithm of the router, which selects the next hop for the datagram. The router forwards each datagram towards its final destination. A datagram travels from one router to another until it reaches a router connected to the destination. Each intermediate router along the end-to-end path selects the next hop used to reach the destination. The next hop represents the next router along the path to reach the destination. This next router can be located on any of the physical networks to which the intermediate router is attached. If it is a physical network other than the one on which the host originally received the datagram, then the result is that the intermediate router has forwarded the IP datagram from one physical network to another. An "IP routing table" in each router is used to forward datagrams between networks. A basic IP routing table comprises information about the locally attached networks and the IP addresses of other routers located on these networks, plus the networks they attach to. A routing table can be extended with information on IP networks that are farther away, and can also comprise a default route, but it still remains a table with limited information. A routing

table represents only a part of the whole IP networks. A router having such a routing table is called "a router with partial routing information". A robust routing protocol must provide the ability to dynamically build and manage information in the IP routing table. As the changes in the network topology may occur, the routing tables

5 must be updated with minimal or without manual intervention.

IP Path

When a datagram is sent to a remote destination, the succession of hops that the datagram flow through, form what is called an IP path. The determination of the IP path is essential to understand how the datagram reaches its final destination when

10 sent from an origin end point. Common network problems arise when the path is "broken", that means when one (or more) intermediate router along the path is no more able to properly forward datagrams to the next hop. To fix such a network problem, it is necessary, first, to isolate the problem and then, to identify the first hop that does not perform any more the routing function along the path.

15 Path determination

The problem is therefore to find a way to determine the path that a datagram takes when this datagram is transmitted between two points of an IP network. To ease the description, the point of the network at the origin of the path to identify, will be called "source host", and the point of the network to reach at the end of this path, will be

20 called "destination host". In many cases, routing problems occur between a client who tries to access resources located on a remote server. In simple terms, the object of the present invention is to investigate network problems between a source and a destination host, by identifying the IP path between this source and destination hosts and by determining where this path is broken.

25 Usually, in corporate networks, users don't investigate problems by themselves, and even if they may do it, they have anyway not the sufficient authority and control over the network to fix the problem. In most of the cases, users call a help desk, and the investigation of problems is done by a person named "Network Manager". This

30 Network Manager is generally in a remote location and is has enough authority to fix the network problems. The first task of the Network Manager is therefore to isolate the problem and to determine exactly where the path is broken.

Traceroute

A useful tool commonly used in networks to troubleshoot connectivity problems, is a software application called "traceroute". The traceroute application enables the determination of the route that datagrams follow from a source to a destination host.

- 5 Traceroute is based upon UDP (User Datagram Protocol) and ICMP (Internet Control Message Protocol). Traceroute sends, using UDP, a series of "probe datagrams" to an IP address and waits for an ICMP reply. A datagram with a "Time to Live" (TTL) of 1 is sent to the destination point. The first router to see the datagram decrements the TTL to 0 and returns an ICMP "time exceeded" message.
- 10 The datagram is discarded. In this way, the first router in the path is identified. This process can be repeated with successively larger TTL values in order to identify the series of routers in the path to the destination host. Traceroute actually sends UDP datagrams to the destination point which reference a port number that is outside the normally used range. This enables traceroute to determine when the destination
- 15 host has been reached, that is when an ICMP "port unreachable" message is received.

In other terms, UDP datagrams are sent with monotonically increasing values in the "Time To Live" (TTL) field, and the chosen UDP port is one most likely not to be in use. For each TTL value, the traceroute program sends a fixed number of

- 20 datagrams (usually three), and receives the IP addresses of the routers responding. This process continues until an ICMP "port unreachable" datagram is received or some TTL threshold is reached (usually 30). If a router receives an IP datagram and decrements the TTL to zero, then it returns an ICMP "time exceeded" message.
- 25 If the IP datagram eventually reaches the destination host, an ICMP "port unreachable" message is returned. Combining the information from all the replies the traceroute program can report the whole route.

Investigating network problems is a very common task devoted to Network Managers. A typical situation is when a network equipment (e.g. a customer's workstation) cannot reach another network equipment (e.g. a server). The end user

- 30 (e.g. the customer) will call a help desk, (typically the Network Manager) in charge of

investigating and resolving the problem. The problem for the Network Manager is to have means to perform the investigation of the failure remotely (usually the Network Manager is far away from the customer's workstation).

Tivoli and the Netview console are typical tools for remotely investigating a problem 5 on a network (Tivoli and Netview are trademarks of IBM Corporation). These tools give a view of the network, and of the status of the connections between neighbor network nodes. The availability of the ports on the network nodes are continuously monitored. A failure on a port will be immediately reported on the monitoring screen, and the Network Manager will be informed of the problem. However, a port failure 10 represents only one type of problem among all the problems that can cause a connection failure. Other problems (such as routing table problems in routers) cannot be detected using this type of tools.

This is why the traceroute application is interesting for investigating on a connection failure. By determining the actual path that is used by the datagrams in the network, 15 and by indicating where this path is broken, traceroute allows a fast problem determination and failure isolation.

However, the usage of the traceroute application suffers from a major drawback. To execute on a computer or a system, a program such as traceroute, the Network Manager needs to take the control of the source host, either directly or remotely 20 (remote logon). This implies the definition and usage by the Network Manager of passwords to take the control of the end user's workstation. The problem is that the the end user (e.g. the customer), for instance, is not necessarily ready to allow a third person to have access to his workstation for simple confidentiality reasons. The access by the Network Manager to a customer's workstation may be considered as 25 an intrusion.

Objects of the invention

It is an object of the present invention is, in case of failure between a source host and a destination device of an IP network, to enable a Network Manager to retrieve information concerning the transmission path (similar to the information provided by 30 the traceroute application), without having to take control of the source device.

Summary of the invention

As defined in independent claims, the present invention is directed to a system, a method, and a computer program in an Internet Protocol (IP) network comprising a plurality of IP network devices, for enabling a remote network manager station to
5 retrieve information related to the transmission path of datagrams sent by a computer device acting as source host to a destination host. The method, for use in a computer system connected to the IP network, comprises the steps of :

- receiving from a network manager station, a message for retrieving information related to the transmission path of datagrams to a destination host;
- 10 • retrieving from this message :
 - a destination address, said destination address being the IP address of the destination host;
 - a source address, said source address being the IP address of the network manager device;
- 15 • sending one or a plurality of probe datagrams to each IP network device along the transmission path to the destination host, each probe datagram comprising :
 - as destination address, the IP address of the destination host;
 - as source address, the IP address of the network manager station;so that a reply, if any, to said probe datagram is directly sent back to the network
20 manager station by the IP network device along the transmission path.

Further embodiments of the invention are provided in the appended dependent claims.

The foregoing, together with other objects, features, and advantages of this invention can be better appreciated with reference to the following specification,
25 claims and drawings.

Brief description of the drawings

The novel and inventive features believed characteristics of the invention are set forth in the appended claims. The invention itself, however, as well as a preferred

mode of use, further objects and advantages thereof, will best be understood by reference to the following detailed description of an illustrative detailed embodiment when read in conjunction with the accompanying drawings, wherein :

- **Figure 1** shows a classical technique used by Network Managers to monitor the availability of networks by testing the interfaces of network devices.
- **Figure 2** shows a typical technique used by Network managers to determine the path between two points of a network.
- **Figure 3** shows a typical situation where a client device tries to connect to a server through a network having a failure on a connection.
- 10 • **Figure 4** shows how the traceroute program determines the path from a client towards a server and locates the first failure along this path.
- **Figure 5** shows the structure of the IP header of an IP datagram, said IP header comprising in particular the TTL and source address fields.
- **Figure 6** shows how the path between the client and the server and the position 15 of the first network failure along the path are determined and how the information is sent back to the Network Manager according to the present invention.
- **Figure 7** is a flow chart showing the transfer of information between the different network devices (source and destination devices, routers along the IP path) and the Network Manager according to the present invention.

The following description is presented to enable one of ordinary skill in the art to make and use the invention and is provided in the context of a patent application and its requirements. Various modifications to the preferred embodiment and the generic principles and features described herein will be readily apparent to those

skilled in the art. Thus, the present invention is not intended to be limited to the embodiment shown but is to be accorded the widest scope consistent with the principles and features described herein.

Path determination between a client and a server from a Network Manager

5 The present invention discloses a system and method to determine the transmission path of a datagram between two points in the network (a source host and a destination host) and more particularly between a client and a server, from a point (a Network Management device or station) distant from the source host (the client station). An object of the present invention is to achieve this determination without

10 having to :

- take control of the source host (client station) and
- manage remote logons (authorization, access lists, passwords, access control, etc...).

For clarity reasons, in the present description, the source, destination and Network

15 Management devices involved in the invention will be named "client station", "server station", and "Network Manager station". It is important to note that this convention must not be interpreted as limitative and that in further embodiments of the invention, the involved devices might perform different roles within the network.

The method for determining the transmission path of datagrams in a network and
20 detecting a failure on this path according to the present invention comprises the following steps :

- The Network Manager station sends a message (IP datagram) to the client station (source host) to determine the path between this client station and a server station (destination host). This message comprises the IP address of the
25 server station.
- The client station receives the message sent by the Network Manager station and retrieves from this message the following information :
 1. the IP address of the server station (destination host);

2. the IP address of the Network Manager station (source IP address of the incoming message);
- The client station then sends using UDP (User Datagram Protocol), a series of "probe datagrams" to the IP address of the server station (destination host). IP datagrams carrying the UDP datagrams are sent with monotonically increasing values in the "time to live" (TTL) field of the IP header. For each TTL value, a fixed number of datagrams are sent. However instead of inserting in each outgoing datagram, its own source address (client station IP address), the client station inserts the IP address of the Network Manager station as source address.
- 5 This operation is called "spoofing".
 - If a router receives one of the IP datagrams sent by the client station and decrements the TTL to zero, then this router returns an ICMP (Internet Control Message Protocol) "time exceeded" datagram. The datagram returned is sent back according to the source address of the datagram. In this case, the returned 15 datagram is directly sent back to the Network Manager station, thanks to the spoofing technique described in the previous paragraph.
 - If an IP datagram sent by the client station, eventually reaches the server station (destination host), an ICMP "port unreachable" datagram is returned to the Network Manager station.
- 20 In the meantime the Network Manager station, combining the information from all the replies, can report the whole route up to the point where the first network failure occurs.

Network monitoring using Ping application

There are two simple and widely used applications that are based on ICMP : Ping 25 and Traceroute. Ping uses the ICMP Echo and Echo reply messages to determine whether a host is reachable. Ping is the simplest of all TCP/IP applications. It sends one or more IP datagrams to a specified destination host requesting a reply and measures the round trip time.

Figure 1 shows a classical method based on the Ping application to monitor, from a 30 remote Network Manager station (103), the availability of a network connection

between a client station (104) (source host) and a server station (105) (destination host).

This method comprises the following steps :

- From its work station, the Network Manager (Help Desk) (103) sends a probe IP datagram called "ping" (more properly named "Echo Request") towards each physical interface (port) of the network devices located on the path that the Network Manager wants to verify (101).
- Upon reception of this datagram (if the interface is operational), each network device sends back a reply (sometimes called "Ping Response" but more properly named "Echo Reply") (102).
- The Network Manager station waits for the network devices' replies. A reply is received when the network device is operational. In case of failure, no reply is received and the Network Manager station displays a "timeout" message after a given period of time.

By checking all individual interfaces along the path, the Network Manager can know whether or not the interfaces are working properly. However, this method has some draw backs. In complex networks, the path taken by datagrams between a client station and a server station is not always known : many different paths can be taken, and the selected path depends on complex IP routing mechanisms. Furthermore, the path can be chosen dynamically, if a dynamic routing protocol is used. Thus, it is sometimes difficult to correlate an interface failure with a connection problem : the interface failure can be unrelated to the problem when for instance this failure is not on the path. It is absolutely necessary to determine the path before verifying whether or not the interfaces along said path are working properly. In addition, a connection may be broken at a logical level while all physical interfaces are operational. If, for example, the routing function of one of the intermediate network devices along the path is not properly working, datagrams may be lost, although all interface are correctly working. This is the reason why, it is very useful to have means to determine the path that is actually used by the datagram flow.

Determination of a datagram path with traceroute

Figure 2 Shows a classical method based on the traceroute application used by Network Managers to determine the path used by a datagram sent by a client to a server. The Network Manager first takes control of the client station with a remote 5 login (101). Then, the Network Manager launches in the client station, the traceroute program. As described earlier, an object of the traceroute program is to send probe datagrams along the path leading to the server station (209), causing each of the intermediate network devices (nodes, routers, ...) (210) to send back a reply ((202) to (206)). The client station (208) gathers the replies sent by the network devices, 10 determines the entire path and transmits the information to the Network Manager (Help Desk) (207) .

Failure on the path between client and server

Figure 3 shows a typical situation where a client station (303) tries to reach a server station (304) without success due to a failure in the network. The path taken by the 15 datagram is symbolized by the arrows (301). This path is interrupted at the point (302) where the network is broken. At this point, datagrams cannot be further transmitted.

Failure investigation with traceroute

Figure 4 shows how the traceroute application operates to investigate a failure in a 20 network according to prior art.

- Probe datagrams are sent by the client station towards the server station.
- Intermediate network devices (nodes, routers, ...) reply to the client station, up to the network failure (401 to 403)
- The client station collects the replies and determines the network path up to the 25 network failure.

The last datagram sent by the client station, reaches the network failure and is lost. No reply (404) is sent back to the client station. After a predefined time period, the client station considers that a network failure is present just after the path partially identified. The information is forwarded to the Network manager which can easily 30 and quickly locate the failure.

Spoofing technique

Figure 5 shows the structure of an IP datagram header. The meaning of the fields comprised in the IP header, is the following:

- **VERS** : This field identifies the IP protocol version.
- 5 • **HLEN** : The length of the IP header counted in 32-bit quantities. This length does not include the data field.
- **Service Type**: The service type is an indication of the quality of service (QoS) requested for the IP datagram.
- **Total Length** : The total length of the datagram, header and data.
- 10 • **Identification** : A unique number assigned by the sender to aid in reassembling a fragmented datagram. Each fragment of a datagram has the same identification number.
- **Flags** : This field comprises control flags
- **Fragment Offset** : This field is used to aid in reassembling the full datagram.
- 15 The value of this field is the number of 64-bit segments (header bytes are not counted) that are contained in earlier fragments. If this is the first (or only) fragment, this field has a value of zero.
- **Time to Live (TTL)** : This field specifies the maximum time period (in seconds) during which the datagram can travel. Theoretically, each router processing this
- 20 datagram is supposed to subtract its processing time from this field. In practice, a router processes the datagram in less than 1 second. Thus the router subtracts one from the value indicated in this field. The TTL has become a hop-count metric rather than a time metric. When the value reaches zero, it is assumed that this datagram is traveling in a closed loop and is discarded. The initial value should be set by the higher level protocol that creates the datagram.
- 25 • **Protocol Number** : This field indicates the higher level protocol to which IP should deliver the data in this datagram.
- **Header Checksum** : This field is a checksum for the information contained in the header. If the header checksum does not match the contents, the datagram is discarded.
- 30 • **Source IP Address** : The 32-bit IP address of the host sending this datagram.
- **Destination IP Address** : The 32-bit IP address of the destination host for this datagram.

Among the IP header fields described here above, the source address is especially interesting in regards to the present invention. This address is normally the IP address of the device that has originated the datagram. This IP address is used by a number of programs which need to know the origin of the datagrams. For example

5 a program which needs to send a message of error back to the originator of the datagram will use this IP address. This is the case with the error message sent back when the time to live field (TTL) reaches zero. This mechanism is used by the traceroute application, in particular, to collect the replies to its probe datagrams.

The spoofing technique consists in changing the source IP address of the datagram

10 to make the programs processing the datagram, think that the origin of the datagram is different than what it is in reality. Especially, the error messages are sent back to the new spoofed address and not to the real originator (source host) of the datagram.

Method for determining the path and the failure along the path according to

15 the present invention

Figure 6 shows how the path between the client station (610) and the server station (611) and the position of the first failure (609) along the path are determined and how the information is sent back to the Network Manager station (612) according to the present invention. The method comprises the following steps :

20 • A message (601) is sent from the Network Manager station (612) to the client station (610) to launch the process .

• Upon reception of the message (601) sent by the Network Manager station, the client station sends probe datagrams towards the server station (611) with increasing TTL values similarly to the traceroute program (602 to 604) . In

25 addition the spoofing technique is use to insert in the probe datagrams, as source address, the IP address of the Network Manager station (instead of the IP address of the client station).

• The intermediate routers (613) send their replies back (when TTL = 0) according to the traceroute mechanism already described. However; because the

intermediate routers use the spoofed address inserted in the probe datagrams, the replies (606 to 608) are directly sent back to the Network Manager station.

- The replies are collected by the Network Manager station, which determines the first part of the path up to the network failure (or the complete path up to the server station if there is no network failure) .
- The last probe datagram (605) sent by the client station (610) reaches the network failure (609) and is lost. The Network Manager station is then able to display the network path up to the network failure (609).

Figure 7 is a flow chart of the process showing the interaction between the various components of the network.

- The Network Manager station (708) sends a command (701) to the client station (709) to start the process and then waits for the replies (702) sent back by routers (702).
- The client station (709), upon reception of the start command (701), sends the probes datagrams (703 705 707 etc...) with as source address, the spoofed address of the Network Manager station (708) and as destination address, the IP address of the server station.
- The intermediate routers (710) reply back directly to the Network Manager station (704, 706, etc...) when the TTL = 0.
- The replies (702) are collected by the Network Manager station.
- At the end of the process, the Network Manager station (708) displays (706) the path that has been computed based on the replies sent by the routers (710).

While the invention has been particularly shown and described with reference to a preferred embodiment, it will be understood that various changes in form and detail may be made therein without departing from the spirit, and scope of the invention.

THIS PAGE BLANK (USPTO)

Claims

What we claim is:

1. a method, for use in a computer device connected to an Internet Protocol (IP) network comprising a plurality of IP network devices, for enabling a remote network manager station to retrieve information related to the transmission path of datagrams sent by said computer device acting as source host to a destination host connected to said IP network, said method comprising the steps of :
 - receiving from a network manager station, a message for retrieving information related to the transmission path of datagrams to a destination host;
 - 10 • retrieving from this message :
 - a destination address, said destination address being the IP address of the destination host;
 - a source address, said source address being the IP address of the network manager device;
 - 15 • sending one or a plurality of probe datagrams to each IP network device along the transmission path to the destination host, each probe datagram comprising :
 - as destination address, the IP address of the destination host;
 - as source address, the IP address of the network manager station;so that a reply, if any, to said probe datagram is directly sent back to the network manager station by the IP network device along the transmission path.
 - 20
2. The method according to the preceding claim wherein the step of sending one or a plurality of probe datagrams to each IP network device, comprises the further steps of :
 - inserting a value in each probe datagram sent to an IP network device, each 25 value being associated with a single IP network device along the transmission path according to a determined increasing order.

3. The method according to any one of the preceding claims wherein the step of inserting a value in each probe datagram sent to an IP network device, comprises the further step of :

5 • inserting said value in the "time to live" (TTL) field of the IP header of each said probe datagrams, said value being decremented by each IP network device along the transmission path.

4. The method according to any one of the preceding claims wherein said probe datagrams fully comply the traceroute protocol except the source address in the IP header which is replaced by the IP address of the network manager station.

10 5. The method according to any one of the preceding claims wherein said IP network devices are IP routers.

6. The method according to any one of the preceding claims wherein :

- said destination host is a server station; and
- said source host is a client station.

15 7. A system comprising means adapted for carrying out the steps of the method according to any one of the preceding claims.

8. A computer program comprising instructions for carrying out the method according to any one of the claims 1 to 6 when said computer program is executed of the system according to the preceding claim.

METHOD AND SYSTEM FOR DETERMINING THE PATH BETWEEN TWO POINTS OF AN IP NETWORK OVER WHICH DATAGRAMS ARE TRANSMITTED

Abstract

5 The present invention is directed to a system, a method, and a computer program in an Internet Protocol (IP) network comprising a plurality of IP network devices, for enabling a remote network manager station to retrieve information related to the transmission path of datagrams sent by a computer device acting as source host to a destination host. The method, for use in a computer system connected to the IP

10 network, comprises the steps of :

- receiving from a network manager station, a message for retrieving information related to the transmission path of datagrams to a destination host;
- retrieving from this message :
 - a destination address, said destination address being the IP address of the destination host;
 - a source address, said source address being the IP address of the network manager device;
- sending one or a plurality of probe datagrams to each IP network device along the transmission path to the destination host, each probe datagram comprising :
 - as destination address, the IP address of the destination host;
 - as source address, the IP address of the network manager station;so that a reply, if any, to said probe datagram is directly sent back to the network manager station by the IP network device along the transmission path.
